The selected image I chose was the garden with trees in the background and multiple bushes that were shaped into cones and a hedge that separates the bushes from the trees. For the foreground, there are three very close trees that were shaped into cones. Therefore for proper replication cones would be used or possibly a tapered cylinder as these trees and bushes are not very pointy. For the center of the image there is a single tree that has multiple rings and what seems to be a torus that surrounds the tree multiple tourus and a tapered cylinder may be used to recreate this and with proper texturing or possibly extruding the cone would allow for a proper one to one recreation of the image. The hedges would be elongated boxes turned into squares and would be transformed into rectangles. For the trees in the background this would arguably be the hardest part to recreate. I have created a tree in Maya before and the way I performed this was by using a cylinder, extruding its faces, and using cones for the leaves. Multiple cylinders and cones would need to be used and a 2D texture of images with a transparent background could be used to replace the flattened cones. Of course to hold everything up a plane would be needed as a way to replicate the ground itself.

The central tree with rings would be a great example of a complex object with multiple shapes, a tapered cylinder for the trunk, multiple tori to simulate the rings and then the torus that surrounds the base. To help simplify the 3D model possibly removing the background trees or using a 2D image to replace the background tree and simulate the image would be a good way to recreate the scene. Possibly combining bushes and hedges and reusing the models and shapes to allow for easily recreatable objects would allow for a great time save.
